

## Answers to suggested problems in Chapter 14

### 14.1b

Note: make sure you include brackets (or parentheses) and “n”

### 14.2

- 100 g/mol
- 100 g/mol
- 226 g/mol
- 192 g/mol

### 14.3 4800

### 14.4

- 42 g/mol
- 631,000 g/mol

### 14.11

#### 2D-drawing representation:

**SYNDIOTACTIC:**  $\text{CH}_3$ 's perfectly alternate “up” and “down”

**ATACTIC:**  $\text{CH}_3$ 's are randomly “up” and “down”

**ISOTACTIC:** All  $\text{CH}_3$ 's are “up” (same)

#### 3D-drawing representation:

$\text{CH}_3$ 's perfectly alternate “forward” (solid wedge) and “back” (dashed wedge)

$\text{CH}_3$ 's are randomly “forward” (solid wedge) and “back” (dashed wedge)

$\text{CH}_3$ 's are all “forward” (solid wedge).  
Alternatively, all  $\text{CH}_3$ 's could be “back” (dashed wedge)

### 14.3

(a) Thermoplastic polymers (thermoplastics) melt (soften) when heated and harden when cooled; they can be melted (softened) and reshaped. Thermosetting polymers cannot be melted and reshaped; once they are “hardened” (in this case, they harden because they were cured/crosslinked), they cannot be melted (softened) with heat. (Note, if you heat a thermosett to the point it melts, it has undergone *decomposition* so that chemical bonds are actually being broken).

(b) Thermoplastic polymers are linear or branched (not crosslinked). Thermosetting polymers are covalently (chemically) crosslinked (networked).

### 14.22

With increasing MW, the polymer chains become longer and so it is too difficult for regions of these “big” chains to “detangle” and then align themselves into ordered crystalline domains.
